(54) Title: ANTIPSYCHOTIC COMBINATION THERAPIES AND COMPOSITIONS OF AN ALPHA-2 ADRENERGIC RECEPTOR ANTAGONIST AND AN ATYPICAL ANTIPSYCHOTIC NEUROLEPTIC

(57) Abstract: The present invention provides novel antipsychotic therapies and compositions useful therein and provides methods for identifying new candidate molecules for the treatment of psychosis based on the proportional binding affinities for α_2 adrenergic and D₂ dopamine receptors.

WO 2004/011031 A1

ANTIPSYCHOTIC COMBINATION THERAPIES AND COMPOSITIONS OF AN ALPHA-2 ADRENERGIC RECEPTOR ANTAGONIST AND AN ATYPICAL ANTIPSYCHOTIC NEUROLEPTIC

This application claims priority to U.S. Provisional Application Nos. 60/398,718, filed July 29, 2002, 60/398,719, filed July 29, 2002, 60/398,720, filed July 29, 2002, 60/402,542, filed August 12, 2002, 60/433,781, filed December 17, 2002, 60/433,782, filed December 17, 2002, and 60/433,785, filed December 17, 2002. The entire contents of these applications are hereby incorporated by reference into the present specification.

10

FIELD OF INVENTION

The present invention relates to improved antipsychotic therapeutic regimens that enable dose reduction and reduce the threshold of D₂ dopamine receptor occupancy required for an effective antipsychotic response and compositions for use therein. In particular, the present invention relates to therapies that involve the administration of a α_2 adrenergic receptor antagonist and an antagonist of D₂ dopamine and the 5HT₂ receptors to produce an improved treatment for serious psychotic mental illness.

20

BACKGROUND OF INVENTION

All patents and publications cited herein are incorporated by reference in their entirety. Full citations are provided at the end of the specification.

Conventional antipsychotics, also termed "typical antipsychotics" are effective in improving symptoms of schizophrenia and are characterized by their antagonist affinity for the D₂ dopamine receptor (see Creese et al, 1979 and Seeman et al, 1976). This pharmacological effect results in acutely diminished activity of the brain's dopamine neurotransmitter systems (Snyder et al 1976). Conventional antipsychotics can be classified into high, medium and low potency based on their proportional affinity for the D₂ receptor. Conventional or "typical" antipsychotics include chlorpromazine, fluphenazine, haloperidol, loxapine, mesoridazine, molindone perphenazine, pimozide, thioridazine, thioxthixene, trifluoperidone (The Merck Manual of Diagnosis and Therapy, 17th Edition, pp1563-1573, 1999). Significant numbers of patients suffering from schizophrenia and other psychoses have proven resistant to treatment with

conventional antipsychotics. Moreover, conventional antipsychotics produce movement related adverse effects related to disturbances in the nigrostriatal dopamine system. These extrapyramidal side effects (EPS) include Parkinsonism, akathisia, tardive dyskinesia and dystonia. See Baldessarini and Tarazi in
5 Goodman & Gilman's The Pharmacological Basis of Therapeutics 10th Edition, 2001, pp485-520.

"Atypical" antipsychotics refer to antipsychotic drugs that produce antipsychotic effects with little or no EPS and include clozapine, risperidone, olanzapine, quetiapine, ziprasidone and aripiprazole. "Atypical" antipsychotics
10 differ from conventional antipsychotics in their pharmacological profiles. While conventional antipsychotics are characterized principally by D₂ dopamine receptor blockade, atypical antipsychotics show antagonist effects on multiple receptors including the 5HT_{2a} and 5HT_{2c} serotonin receptors and varying degrees of receptor affinities. See Meltzer in Neuropsychopharmacology: The Fifth
15 Generation of Progress, 2002, pp 819-831; Meltzer et al. 1989; and Baldessarini and Tarazi in Goodman & Gilman's The Pharmacological Basis of Therapeutics 10th Edition, 2001, pp485-520. Atypical antipsychotic drugs are commonly referred to as serotonin/dopamine antagonists, reflecting the influential hypothesis that greater affinity for the 5HT₂ receptor than for the D₂ receptor underlies
20 "atypical" antipsychotic drug action or "second generation" antipsychotic drugs (Meltzer et al, 1989).

The most precise distinction between typical and atypical antipsychotics is the dissociation of conditioned avoidance response (CAR), an animal model of psychosis, from catalepsy (CAT), the animal model of EPS. While conventional
25 antipsychotic drugs produce CAT and suppression of CAR at roughly equivalent doses, atypical antipsychotics suppress CAR at doses at least 2 fold lower than doses that produce CAT. See Meltzer in Neuropsychopharmacology: The Fifth Generation of Progress, 2002, pp 819-831; Arnt and Skarsfeld, 1998). It has been shown that CAT and CAR models have high predictive value because
30 they share occupancy of the D₂ receptor as an underlying mechanism. Dissociation of CAT from CAR translates into a clinical profile of an antipsychotic drug that produces EPS at doses that produce $\geq 80\%$ in vivo D₂ occupancy with antipsychotic effects $\leq 70\%$ D₂ occupancy. See Wadenberg et al., 2000, 2001.

Clozapine is the only antipsychotic drug with proven efficacy in treatment-refractory schizophrenia, with efficacy rates in treatment-refractory patients ranging from 20% to 70% and a therapeutic profile that includes reduction in suicide risk (See Kane et al, 1988; Pickar et al 1992; Pickar et al 2003; Miyamoto et al, 2001; Chakos et al, 2001; Meltzer et al, 2003). Unlike other atypical antipsychotics, clozapine is an effective antipsychotic with in vivo D₂ occupancy in the range of 50-60% considerably less than olanzapine (70%) and risperidone ($\geq 70\%$) See Farde et al, 1992; Nyberg et al, 1993, Pickar et al 1996; Su et al 1997; Nordstrom et al 1998; Kapur et al 1999. High levels of D₂ occupancy ($\geq 70\%$) are associated with EPS, dysphoria and poor subjective experience (see Kapur et al 2000 and Haan et al 2003). Antipsychotic potency with low in vivo D₂ occupancy is a highly desirable model for future antipsychotic drugs (See Kapur and Seeman, 1999). Consistent with its clinical profile, clozapine demonstrates pronounced separation of CAT from suppression of CAR in animal models (See Waddenberg et al 2000 and 2001).

Pharmacologically, clozapine differs from other atypical antipsychotics by antagonist affinity for the α_2 -adrenergic receptor that exceeds its affinity for the D₂ receptor. Thus, while clozapine demonstrates about 1–4 fold greater affinity for α_2 receptor than D₂ receptor other atypical agents show markedly less affinity for the α_2 adrenergic receptor than for the dopamine D₂ receptor. For example, risperidone: 2-16 fold less, olanzapine: 8-21 fold less, quetiapine: 6-16 fold less, ziprasidone: 100 fold less, and aripiprazole: 23 fold less. See Baldessarini and Tarazi in Goodman & Gilman's The Pharmacological Basis of Therapeutics 10th Edition, 2001, p 495; Miyomota in Neuropsychopharmacology: The Fifth Generation of Progress, 2002, p. 778; Shapiro et al, 2003. It was previously disclosed in two patents by Pickar et al. that serious psychotic disorders can be effectively treated using a combination of an α_2 adrenergic receptor antagonist and a D₂ dopamine receptor antagonist (see U.S. Patent 5,492,907 and U.S. Patent 5,663,167; Litman et al 1996; Hertel et al. 1999. Further, Broekkamp et al, U.S. Patent No. 6,150,353, disclose combinations of the antidepressant mirtazapine with typical and atypical antipsychotic agents for the treatment of psychotic disorders.

The use of clozapine, however, is associated with severe side effects, including agranulocytosis, seizures, weight gain and diabetes. Weight gain and

increased diabetes risk are adverse effects of olanzapine, while increased prolactin secretion is an adverse effect of risperidone.

Therefore, it is an object of the present invention to provide an effective method of treatment for patients suffering from serious psychotic mental illness who remain symptomatic despite treatment with drugs that block the D₂ dopamine and 5HT₂ serotonin receptors.

It is another object of the present invention to provide a method of treatment which does not have the severe side effects associated with the administration of clozapine.

It is a further object of the present invention to provide a means to minimize adverse events of atypical antipsychotics by enabling dose reduction and antipsychotic effectiveness at $\leq 70\%$ in vivo D₂ occupancy.

It is yet another object of the present invention to provide pharmaceutical compositions and means for discovery of further compounds useful in foregoing methods of treatment.

Other objects, features and advantages of the present invention will become apparent to those skilled in the art from the following detailed description. It is to be understood, however, that the detailed description and specific examples, while indicating preferred embodiments of the present invention, are given by way of illustration and not limitation. Many changes and modifications within the scope of the present invention may be made without departing from the spirit thereof, and the invention includes such modifications.

SUMMARY OF THE INVENTION

The present invention provides a method for treating a serious psychotic mental illness comprising the step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of (i) an α_2 - adrenergic receptor antagonist and (ii) an atypical antipsychotic which has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor in a pharmaceutically acceptable carrier.

The invention further provides a pharmaceutical composition comprising a combination of (i) an α_2 -adrenergic receptor antagonist, (ii) an atypical antipsychotic which has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor, and (iii) a pharmaceutically

acceptable carrier, wherein the amount of said ingredients (i) and (ii) is therapeutically effective against serious psychotic mental illness.

The invention also provides a method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a combination of (i) a compound having combined D₂ dopamine and 5HT₂ serotonin antagonist activities, wherein said compound (ii) has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor and (ii) a compound having α_2 adrenergic receptor antagonist activity.

10 In one embodiment, the invention provides a method for treating a serious psychotic mental illness comprising the step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of idazoxan and olanzapine.

The invention also provides a method for treating a serious psychotic mental illness in a patient in need thereof which comprises co-administration of (i) a compound having combined D₂ dopamine and 5HT₂ serotonin antagonist activities, wherein said compound has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor, and (ii) a compound having α_2 adrenergic receptor antagonist activity, wherein said compound (i) is administered initially alone in an amount and for a period of time sufficient to stabilize said patient and subsequently said compound (ii) is co-administered in an amount and for a period of time that allows for a reduction in the amount of compound (i) administered to said patient.

25 The invention also provides a method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a combination of (i) a compound that blocks or down-regulates D₂ dopamine and 5HT₂ serotonin antagonist activities and (ii) a compound that blocks or down-regulates α_2 adrenergic receptor activity.

30 The invention further provides a method for treating a serious psychotic disorder in a patient in need thereof which comprises administering an atypical antipsychotic in combination with an effective amount of an α_2 antagonist to provide antipsychotic effects at D₂ receptor occupancy levels of less than or equal to 60%.

The invention also provides a method for treating a serious psychotic disorder in a patient in need thereof which comprises administering an atypical D₂ antagonist in combination with an effective amount of a compound which enhances noradrenergic synaptic activity to provide antipsychotic effects at D₂ receptor occupancy levels of less than or equal to 60%.

The invention further provides a method for treating a serious psychotic illness comprising administering at least one atypical antipsychotic and at least one α_2 adrenergic receptor antagonist wherein the dosage balance between the atypical antipsychotic and α_2 antagonist is equivalent to a ratio of 900-1100 mg equivalents of chlorpromazine and an amount of an α_2 antagonist that provides for about equal D₂/ α_2 receptor saturation.

The invention also provides a method for identifying compounds that are useful to treat serious psychotic mental illness which comprises subjecting a candidate compound to an assay demonstrating affinity for the D₂ dopamine receptor and an assay demonstrating affinity for the α_2 adrenergic receptor and determining that the compound demonstrates significant affinity for both the D₂ dopamine receptor and the α_2 adrenergic receptor.

BRIEF DESCRIPTION OF THE FIGURE

20

FIG. 1 depicts the effect of olanzapine (1.25 or 2.5 mg/kg, i.p.) and idazoxan (1.5 mg/kg s.c.) alone and in combination on Conditioned Avoidance Response (CAR) behavior in 9 rats serving as their own controls in a change-over design (Li, 1964). Shown are medians \pm semi-interquartile range. Statistics are shown as * $p < 0.05$, ** $p < 0.01$ (compared to vehicle controls) and ++ $p < 0.01$ (compared to animals treated with olanzapine alone) as assessed by the Wilcoxon matched-pairs signed-ranks test. Idazoxan (1.5 mg/kg s.c.) alone had no effects on CAR performance. No escape failures were noted at any time or in any treatment group.

30

DETAILED DESCRIPTION

It has been discovered that the administration of an α_2 adrenergic receptor antagonist unexpectedly enhances the antipsychotic potency of atypical antipsychotics. This is reflected by an enhanced dissociation of the dose of

atypical antipsychotic required to produce CAT and the dose required to suppress CAR, animal models of EPS and antipsychotic potency, respectively. While atypical antipsychotics such as olanzapine are characterized by some separation of doses required for CAT and CAR, the addition of an α_2 antagonist substantively
5 enhances this effect resulting in a more potent antipsychotic composition without enhancement of EPS liability. The present invention provides for an improved treatment for patients suffering from serious psychotic mental illness who remain symptomatic despite treatment with atypical antipsychotic drugs.

10 Methods of Treatment

As discussed above, it was previously reported by the present inventor that the administration of an α_2 -adrenergic receptor antagonist enhances the therapeutic effect of conventional or "typical" antipsychotic drugs. Particularly, as is the subject of U.S. Patent No. 5,492,907 and U.S. Patent No. 5,663,167 by
15 Pickar et al. it was discovered that the combined administration of an α_2 adrenergic receptor antagonist and a typical or conventional antipsychotic neuroleptic is an effective improvement upon monotherapy with a typical antipsychotic in patients suffering from serious psychotic mental illness. By contrast, the present invention in part involves the discovery that serious psychotic
20 illnesses can be improved by the administration of an atypical antipsychotic drug and an α_2 adrenergic receptor antagonist. Further, the invention discovers that the addition of an α_2 antagonist to an atypical antipsychotic, by enhancing the separation between EPS liability and antipsychotic effectiveness, enables dose reduction of the atypical antipsychotic drug such that therapeutic effects can be
25 gained with an in vivo D_2 occupancy $\leq 60\%$. On the basis of these discoveries, the invention provides for a model for high throughput screening of drug molecules to identify agents with enhanced antipsychotic potency.

"Atypical" antipsychotic drugs are distinguished from "typical" or conventional antipsychotic drugs on the basis of the dissociation of EPS liability
30 from antipsychotic effectiveness as demonstrated in animal models (e.g., CAT and CAR) and in the clinic. Pharmacologically, "atypical" antipsychotic drugs differ prominently from conventional antipsychotics by displaying diverse pharmacological effects on multiple neurotransmitter systems, characteristically antagonist properties to both the D_2 and D_3 dopamine receptors and the $5HT_{2a}$ and

5HT_{2c} serotonin receptors and include olanzapine, quetiapine, ziprasidone, aripiprazole, sertindole and risperidone. In the present invention, "atypical" antipsychotic drugs exclude, clozapine, an antipsychotic with a unique therapeutic profile and with antagonist affinity for the α_2 adrenergic receptor that equals or exceeds the affinity for the D₂ dopamine receptor. Clozapine is associated with severe side effects including agranulocytosis, seizures and diabetes.

Examples of "typical" antipsychotic drugs include those referred to as "typical neuroleptics" such as chlorpromazine, fluphenazine, trifluoperazine, haloperidol, perphenazine, chlorprothixene, thioxine, bromperidol, loxapine and molindone.

The term "serious psychotic mental illness" denotes conditions in which delusions and/or hallucination and other manifestations of deficits in reality testing are present in conjunction with negative symptomatology. See Diagnostic and Statistical Manual, 4th Edition Text Revision, 2000 (DSM-IV), American Psychiatric Association, Committee on Nomenclature and Statistics (Washington, DC, American).

Typical symptoms associated with serious psychotic mental illnesses, include, inter alia, the sudden or insidious onset of delusions or hallucinations, disorganized speech (e.g., frequent derailment or incoherence), grossly disorganized or catatonic behavior, paranoia, and major manic, depressive or mixed episodes. Illustrative of serious psychotic mental illnesses are schizophrenia, schizoaffective illnesses, brief psychotic disorders which involve the sudden onset of delusions or hallucinations, disorganized speech or grossly disorganized or catatonic behavior. Individuals experiencing brief psychotic disorders typically experience emotional turmoil or overwhelming confusion, may have rapid shifts from one intense affect to another, and typically exhibit poor judgment, cognitive impairment or actions based on delusions.

Within the context of the present invention, "serious psychotic mental illness" also includes Bipolar I disorders typically manifested by individuals who have previously experienced at least one manic episode or mixed episode and who later manifest a manic, hypomanic, mixed or a major depressive episode which cause clinically significant distress or impairment in social, occupational or other important areas of functioning. The mood symptoms of Bipolar I disorders are not due to the direct physiological affects of substance abuse or medication and

are not better accounted for by schizoaffective disorder and are not superimposed on schizophrenia, schizophreniform disorder, delusional disorder or psychotic disorder not otherwise specified.

Serious psychotic mental illness also pertains to psychotic disturbances
5 related to specific general medical conditions and to dementias including dementia of the Alzheimer's Type and Parkinson's disease. These behavioral disturbances may take the form of hallucinations, delusions, grossly disorganized and aggressive behavior. There may be multiple medical causes or multiple types of dementia present.

10 In sum, serious psychotic mental illnesses include, inter alia, Schizophreniform Disorder, Schizoaffective Disorder, Severe Schizoaffective Disorder with psychotic features, Bipolar I disorders with a Single Manic Episode, Severe Bipolar I disorders with Psychotic Features, Bipolar I Disorders Manifesting a Mixed Most Recent Episode, Severe Bipolar I Disorders with
15 Psychotic Features, Brief Psychotic Disorders, Psychotic Disorders NOS, Paranoid Personality Disorders, Schizoid Personality Disorders, Schizophrenia, Schizotypal Personality Disorders with Sedative, Hypnotic, or Anxiolytic Manifestations, Major Depressive Disorders with Psychotic Features and Psychotic Disorders due to Specific General Medical Conditions.

20 In a preferred embodiment, the serious psychotic disorder treated by the methods of this invention is child or early adolescent schizophrenia, in particular treatment of patient of about age 9 years to 15 years, and/or wherein the serious psychotic disorder is childhood onset schizophrenia. Childhood or early adolescent onset schizophrenia typically refers to schizophrenia showing onset
25 from about age 9 to about age 15 years.

Preferably, the α_2 adrenergic receptor antagonist utilized according to the invention is a selective antagonist, i.e., a drug whose principal pharmacological effect in vitro is antagonism of α_2 adrenergic receptors without direct pharmacological effects on serotonin or dopamine receptors. A particularly
30 preferred α_2 adrenergic receptor antagonist for use according the invention is idazoxan [\pm -2-(1,4-benzodioxan-2-yl)-d-imidazoline]. Methods of making benzodioxan imidazolines including idazoxan are disclosed in U.S. Patent No. 2,979,511 (Krapcho et al.). Methods of formulating pharmaceutical compositions comprising benzodioxan imidazolines including idazoxan are disclosed in U.S.

Patent No. 4,436,914 (Kluge et al.) Idazoxan is a highly selective α_2 receptor antagonist. (See Doxey et al 1983). Other useful α_2 adrenergic receptor antagonists include ethoxy-idazoxan, yohimbine, fluperoxan, and atipamezole.

In a preferred embodiment of the methods of the invention, the α_2 adrenergic receptor antagonist is administered to a patient undergoing chronic treatment with an "atypical" antipsychotic. This permits assessment of the degree antipsychotic response prior to the administration of the α_2 adrenergic receptor antagonist. Thus the present invention provides a method for treating a serious psychotic mental illness in a patient in need thereof which comprises co-administration of (i) a compound having combined D₂ dopamine and 5HT₂ serotonin antagonist activities, wherein said compound has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor, and (ii) a compound having α_2 adrenergic receptor antagonist activity, wherein said compound (i) is administered initially alone in an amount and for a period of time sufficient to stabilize said patient and subsequently said compound (ii) is co-administered in an amount and for a period of time that allows for a reduction in the amount of compound (i) administered to said patient. The term "stabilize" (in its various grammatical forms) is used herein in the same manner recognized by those of ordinary skill, such as to represent the phase of treatment during which medication is administered at a dose that produces some clinical improvement without the occurrence of limiting adverse events. Determination of the appropriate amounts of compound administered and the duration of treatment to achieve stabilization will vary depending on illness being treated and particular patient and is within the ordinary skill of the art. In the practice of this aspect of the invention, the method may further comprise the step of reducing the amount of compound (i) administered to said patient after commencing co-administration of compound (ii), preferably reduced to approximately 50% of the dose administered to stabilize said patient. In a separate embodiment, the two compounds can be administered together at the beginning of treatment if desired.

In the practice of any of the methods of the invention one or both of the atypical antipsychotic and the α_2 antagonist can be administered as a mixture of enantiomers of said compounds or substantially in the form of a single (+) or (-) enantiomer, when the compound is susceptible to formation of separate enantiomers, i.e., which underlying compound is capable of being produced as a

racemate. As used herein, the term "substantially in the form of a single enantiomer" refers to mixtures of enantiomers that comprise greater than 95/5 up to 100/0 mole ratios of either enantiomer of a racemate. In one embodiment of the methods, the atypical antipsychotic is administered in the form of a mixture of enantiomers which comprises from 95/5 to 5/95 mole ratios of the enantiomers of the particular atypical antipsychotic. In a separate embodiment of the methods the α_2 antagonist mixture comprises from 95/5 to 5/95 mole ratios of the enantiomers of the particular α_2 antagonist compound. For example, these mixtures may comprise any greater molar concentrations of one enantiomer, e.g., up to 95/5, up to 90/10, up to 80/20, up to 70/30, and up to 60/40. Preferably, the atypical antipsychotic and/or α_2 receptor antagonist will comprise the isomeric form which exhibits the best pharmacokinetic properties and/or efficacy.

In the case of idozoxan, a preferred α_2 -adrenoreceptor antagonist compound according to the invention, properties of the two enantiomers of idazoxan have been compared at the pre- and post-synaptic level. (Martire, et al. 1988). Particularly, the antagonism of the two idazoxan stereoisomers was assessed at presynaptic level, by comparing their ability to antagonize clonidine at the alpha 2 adrenoreceptors regulating noradrenaline release. The antagonist (+) - idazoxan was shown to possess an affinity towards the α_2 autoreceptors 40 times higher than that of (-) idazoxan. Binding studies also revealed that (+) idazoxan was 7-8 times more potent in inhibiting the *p*-[³H]aminoclonidine binding. These results indicate a different affinity of α_2 adrenoreceptors for the two idazoxan stereoreceptors and suggest that the α_2 adrenoreceptors located pre and post synaptically may be of different subtypes.

While in such instances, e.g., in the case of idazoxan, one isomer may be preferred, in some cases there may be no difference between the pharmacological properties of different isomers. In the case of idazoxan, the (+) stereoisomer will preferably be used, or a mixture predominantly comprising the (+) isomer, i.e., at least 80/20 ratio of (+)-, more preferably at least 90/10 ratio of +I isomer, and most preferably at least 95/5 ratio of +I isomer. This invention further includes administration to a patient of mixtures of either single enantiomer of a compound, or substantially in the form of either single enantiomer, according to preferred embodiments of the invention, that may nonetheless result in *in vivo* conversion to

racemic or substantially 50/50 mole ratio mixtures of enantiomers, depending on the compound administered.

Preferred dosages of the α_2 -adrenergic receptor antagonist according to the invention range from about 60 to 120 mg/day. Treatment with atypical antipsychotics should be within the recommended dose range prior to the administration of α_2 adrenergic antagonist. Once the desired dose of the α_2 adrenergic antagonist has been reached, the preferred dose of the atypical antipsychotic should be roughly 50% of the normal recommended dose range. In accordance, a 50% reduction in dose ranges for atypical antipsychotics may result in administration of compounds as follows: olanzapine, 5-12 mg/day; risperidone, 2-6 mg/day; Quetiapine, 150-450mg/day; sertindole 2-12/mg/day; ziprasidone, 40-80 mg/day; aripiprazole, 15-30mg/day. The Merck Manual, the Physician's Desk Reference, and individual product prescription information provide adequate disclosure for those of ordinary skill in the art to calculate appropriate dosages, and adequate reduced dosages, of the compounds contemplated for use in the methods of the invention.

In another preferred embodiment of the method according to the invention, the dose of the atypical antipsychotic should be decreased as described above to an endpoint providing for an in vivo D_2 receptor occupancy of 60% is achieved. This level of occupancy for these atypical antipsychotic drugs would only be effective when the α_2 antagonist is co-administered. In vivo D_2 occupancy can be determined using functional brain imaging technologies such as Positron Emission Tomography (PET) or Single Photon Emission Computerized Tomography (SPECT).

Reduction of dose and D_2 occupancy for atypical antipsychotics enabled by the co-administration of α_2 antagonists would reduce risk of dose-dependent adverse events including EPS, weight gain and diabetes.

In one embodiment of the present invention, both the α_2 -adrenergic receptor antagonist and the atypical antipsychotic can be administered in separate form. The two compounds can also be administered in a single pharmaceutical composition, in combination with known pharmaceutically acceptable carriers. Such pharmaceutical compositions thus constitute another aspect of the present invention. These compositions may be prepared from conventional materials by known procedures.

Further, the invention also provides a method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a combination of (i) a compound that blocks or down-regulates D₂ dopamine and 5HT₂ serotonin receptor activities and (ii) a compound that blocks or down-regulates α_2 adrenergic receptor activity.

Examples of compounds that block or down-regulate D₂ dopamine and 5HT₂ serotonin receptor activities include, but are not limited to, compounds such as olanzapine, risperidone, sertindole, aripiprazole and ziprasidone. Examples of compounds that block or down-regulate α_2 adrenergic receptor activity include, but are not limited to, α_2 antagonists, norepinephrine reuptake inhibitors, selective serotonin reuptake inhibitors, and anti-sense DNA or RNA molecules and techniques.

As stated above, clozapine is the most effective of all known antipsychotics in reducing positive and negative symptoms of psychosis in otherwise treatment resistant patterns. The explanation of the enhanced efficacy of clozapine remains uncertain. However, it is known that clozapine, among its pharmacological properties, possesses a relatively equal or greater balance of affinities for α_2 and D₂ receptors. Particularly, in one report the k_i for clozapine for the D₂ receptor is 180 nmol whereas k_i for clozapine for the α_2 receptor is about 160 nmol (Goodman and Gilman, *Pharmacol. Basis of Therapeutics*, 10th Edition, p.495 (2001)).; in another report the k_i of clozapine for the D₂ receptor is reported 130 nM and the K_i for the α_2 receptor is 33 (Miyomota in Neuropsychopharmacology: The Fifth Generation of Progress, 2002, p. 778). These data translate to an estimated relative binding affinity (k_i) for D₂/ α_2 receptors ranging from approximately .88 to 4. Thus, in the practice of the present invention, the appropriate balance of D₂/ α_2 receptor which may be significant to its unique therapeutic effectiveness and the beneficial properties of clozapine may be achieved during combination therapy involving the administration of at least one atypical antipsychotic and α_2 blocker.

More specifically, based thereon, it was theorized that the effectiveness of combination an atypical antipsychotic and α_2 receptor antagonist therapies for treatment of serious psychotic disorders could be improved by (i) selecting specific combinations of atypical antipsychotics and α_2 receptor antagonists such

that the relative D_2/α_2 binding affinity ratios (k_i) range from about 0.80 to about 4.5, more preferably from about 0.85 to about 4.0, more preferably from about 0.90 to about 3.9, and most preferably ranges from about .95 to about 1.05, and preferably a ratio of about 1.0.

5 The selection of atypical antipsychotic and α_2 antagonist combinations that satisfy these binding affinity ratios will result in enhanced therapeutic efficacy of typical and atypical antipsychotics and may provide a similar relative balance of pharmacological effects to that of clozapine. This is an advantage as it will enable administration of reduced dosages thereby minimizing or eliminating adverse side
10 effects such as tardive dyskinesia. This has particularly advantages in the context of treating children and adolescents.

 Alternatively, this may be accomplished by administering the atypical antipsychotic/ α_2 antagonist drug combination at dosages that are selected to offset relative differences in receptor affinities. In this regard, it is known in the art to
15 convert antipsychotic potencies to chlorpromazine equivalents in order to compare antipsychotic dosing with different agents. Chlorpromazine equivalents are in proportion to affinities for the D_2 receptor. The target dose of clozapine is 500mg (1000mg chlorpromazine equivalents) for treatment-resistant patients (*Merck Manual*) 17th Edition, (1999)). 1000mg chlorpromazine equivalents for different
20 D_2 blocker include 20mg fluphenazine; 900mg quetiapine; 24 mg sertindole; and 40mg olanzapine.

 It has been previously reported (Litman et al., *Br. J. Psychiatry* 168:571-9, (1996)) that 1000mg chlorpromazine equivalents of fluphenazine added to a dose of 120mg/day of an α_2 antagonist, idazoxan, have resulted in adequate clinical
25 responses (k_i for α_2 receptor for idazoxan is approximately 30 nM. However, it was not known or previously suggested that clinical responses can be provided with minimization of adverse side effects when using typical or atypical antipsychotic/ α_2 antagonist drug combinations, in particular by selecting relative dosage amounts that provide for approximately the same relative occupation of D_2
30 and α_2 receptors. This is preferably achieved herein by selecting dosages of a antipsychotic drugs that correlates to about 900-1100 chlorpromazine equivalents, more preferably about 950-1050 chlorpromazine equivalents, and most preferably about 1000 chlorpromazine equivalents and an amount of one or more α_2 blockers that provide for equivalent occupation of D_2 and α_2 receptors. A suitable α_2 dosage

can be determined by one skilled in pharmacology and will depend upon factors such as the pharmacokinetic properties of the particular α_2 drug, its α_2 receptor affinity, k_i , rate of absorption, half-life, ability to cross blood brain barrier, and other pharmacokinetic considerations.

5 Dosage equivalents for different antipsychotic drugs that correlate to 1000 mg equivalents of chlorpromazine are identified *supra*. Alternatively, similarly enhanced results may be achieved by combining one or more antipsychotic drugs and/or one or more α_2 antagonists so as to satisfy the above-identified dosage equivalent ratios for the antipsychotic drug and α_2 blocker. The subject improved
10 combination therapies may be used to treat any serious psychotic illness without the adverse side effects of clozapine. In preferred embodiments, the subject combination therapies will be used to alleviate positive and negative symptoms of psychosis in otherwise treatment resistant patients, i.e., patients who have proven resistant to treatment with known typical antipsychotics alone. As mentioned, a
15 preferred usage is for the treatment of pediatric and adolescent schizophrenia. The combination therapies of the invention further contemplate the inclusion of other drugs that enhance the synaptic effects of norepinephrine.

Drug Discovery Methods

20 In another embodiment of the present invention, the discovery of enhancement of antipsychotic effects by α_2 adrenergic antagonist administration to atypical antipsychotic drugs can be utilized for high throughput screening for new antipsychotic drugs. In this embodiment, drugs which show a 1-10 fold greater affinity for the α_2 receptor in comparison with affinity for the D_2 receptor, with or
25 without antagonist effects on serotonergic receptors, are identified as candidates for new antipsychotic drugs. It is expected that high throughput screening may identify such compounds, that will then be tested in CAT and CAR animal models and may subsequently continue development for use in the clinical setting.

The present invention further provides a method for identifying
30 compounds that are useful to treat serious psychotic mental illness which comprises subjecting a candidate compound to an assay demonstrating affinity for the D_2 dopamine receptor and an assay demonstrating affinity for the α_2 adrenergic receptor and determining that the compound demonstrates significant affinity for both the D_2 dopamine receptor and the α_2 adrenergic receptor. To refine the

activities of the compounds identified, the screening method of the invention may comprise the further step of subjecting the candidate compound to an assay demonstrating affinity to 5HT_{2a} serotonin receptor and determining that the compound does not demonstrate significant affinity for the 5HT_{2a} or other forms of the 5HT₂ serotonin receptor.

Assays for determining affinity of candidate compounds for the D₂ dopamine, α_2 adrenergic, and 5HT_{2a} serotonin receptors are readily available to those of ordinary skill in the art and include radioligand displacement assays, reporter gene assays and stereochemical modeling. For example, the following patents describe various screens for determining receptor activity of candidate compounds: U.S. Patent No. 6,342,360 (D₂ dopamine receptor); U.S. Patent No. 5,994,384 (α_2 adrenergic receptor); and U.S. Patent No. 6,140,509 (5HT_{2a} serotonin receptor). In a preferred embodiment, the step of determining that the candidate compound demonstrates affinity for the α_2 adrenergic receptor comprises determining that the compound demonstrates between about 2 to about 15 fold lower k_i for the α_2 adrenergic receptor than for D₂ receptor (k_i nM).

Based on the description of the invention herein, it is clear that the compounds discovered in such methods would represent improved compounds for methods of treating serious psychotic mental illness. Thus, the invention also provides a method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a compound identified by the methods described above. Further, the invention provides a pharmaceutical composition for treating a serious psychotic mental illness comprising a therapeutically effective amount of a compound identified by the methods described above and a pharmaceutically acceptable carrier.

Pharmaceutical Compositions

As stated above, the present invention further provides a pharmaceutical composition comprising a combination of (i) an α_2 -adrenergic receptor antagonist, (ii) an atypical antipsychotic neuroleptic which has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor, and (iii) a pharmaceutically acceptable carrier, wherein the amount of said

ingredients (i) and (ii) is therapeutically effective against serious psychotic mental illness.

Compositions within the present invention can be adapted for oral or parenteral administration, as well as for enteral administration orally or through mucus membranes, that is intranasally, sublingually, buccally or rectally, or may be adapted for slow release formulations.

Compositions for oral administration include capsules, tablets, dispersible powders, granules, syrups, elixirs and suspensions. These compositions can contain one or more conventional adjuvants such as sweetening agents, flavoring agents, coloring agents and preserving agents.

Tablets can contain the active ingredients in a mixture with conventional pharmaceutically acceptable excipients. These include inert carriers, such as calcium carbonate, sodium carbonate, lactose, and talc; granulating disintegrating agents, such as starch, gelatin acacia; and lubricating agents, such as magnesium stearate, stearic acid and talc. Tablets may be uncoated or coated by known techniques to delay disintegration and absorption in the gastrointestinal tract thereby providing a sustained action over a longer period of time.

Capsules may contain the active ingredients alone or an admixture with an inert solid carrier, such as calcium carbonate, calcium phosphate or kaolin. Similarly, suspensions, syrups and elixirs may contain the active ingredients in mixture with any of the conventional excipients utilized in the preparation of such compositions. This includes suspending agents such as methylcellulose, trancanth and sodium alginate; wetting agents such as a lecithin, polyoxyethylene stearate or polyoxyethylene sorbitol monoleate; and preservatives.

The pharmaceutical combination of the invention is administered in a pharmacologically-effective amount to treat any of the conditions described above, and is based on the activity of the combination. The term "pharmacologically-effective amount" means the amount of a drug or pharmaceutical agent that will elicit the biological or medical response of a tissue, system, animal or human that is being sought by a researcher or clinician. It is an amount that is sufficient to significantly affect a positive clinical response while maintaining diminished levels of side effects. The amount of pharmaceutical combination which an α_2 antagonist with a K_i of approximately 40 nM may be

administered to a subject in need thereof can be in the range of 60 to 120 mg/day, or more preferably 120 mg/day. , administered in single or divided doses.

Administration of the dose can be oral, topical, intravenous, subcutaneous, intramuscular, or any other acceptable systemic method. Based on the judgment
5 of the attending clinician, the amount of drug administered and the treatment regimen used will, of course, be dependent on the age, sex and medical history of the patient being treated, the severity of the specific disease condition and the tolerance of the patient to the treatment as evidenced by local toxicity and by systemic side-effects.

10 In practice, the pharmaceutical combinations of the invention are administered in amounts which will be sufficient to inhibit or prevent undesired medical conditions or disease in a subject, such as a mammal, and are used in the form most suitable for such purposes. The compositions are preferably suitable for internal use and include an effective amount of a pharmacologically-active
15 compound of the invention, alone or in combination with other active agents, with one or more pharmaceutically-acceptable carriers. The compounds are especially useful in that they have very low, if any, toxicity.

The pharmaceutical combinations of the invention can form the active ingredient of a pharmaceutical composition, and are typically administered in a
20 mixture with suitable pharmaceutical diluents, excipients or carriers (collectively referred to herein as "carrier" materials) suitably selected with respect to the intended form of administration, that is, oral tablets, capsules, elixirs, syrups and the like. The compositions typically will include an effective amount of active compound or the pharmaceutically-acceptable salt thereof, and in addition, and
25 may also include any carrier materials as are customarily used in the pharmaceutical sciences. Depending on the intended mode of administration, the compositions may be in solid, semi-solid or liquid dosage form, such as, for example, injectables, tablets, suppositories, pills, time-release capsules, powders, liquids, suspensions, or the like, preferably in unit dosages.

30 Conventional pharmaceutical compositions comprising a pharmacologically-effective amount of the pharmaceutical combinations of the invention together with pharmaceutically-acceptable carriers, adjuvants, diluents, preservatives and/or solubilizers may be used in the practice of the invention. Acceptable diluents include diluents of various buffers (e.g., arginine, Tris-HCl,

acetate, phosphate) having a range of pH and ionic strength, carriers (*e.g.*, human serum albumin), solubilizers (*e.g.*, tween, polysorbate), and preservatives (*e.g.*, benzyl alcohol). See, for example, U.S. Pat. No. 4,496,537.

Administration of the pharmaceutical combinations described herein can
5 be via any of the accepted modes of administration for individual therapeutic agents. These methods include systemic or local administration such as oral, nasal, parenteral, transdermal, subcutaneous, or topical administration modes.

For instance, for oral administration in the form of a tablet or capsule (*e.g.*, a gelatin capsule), the active drug component can be combined with an oral, non-
10 toxic pharmaceutically-acceptable inert carrier such as ethanol, glycerol, water, and the like. Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents, and coloring agents can also be incorporated into the mixture. Suitable binders include starch, magnesium aluminum silicate, starch paste, gelatin, methylcellulose, sodium carboxymethylcellulose and/or
15 polyvinylpyrrolidone, sugars, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, polyethylene glycol, waxes and the like. Lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride, silica, talcum, stearic acid, its magnesium or calcium salt, and/or polyethylene glycol and
20 the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum starches, agar, alginic acid or its sodium salt, or effervescent mixtures, and the like. Diluents, include, *e.g.*, lactose, dextrose, sucrose, mannitol, sorbitol, cellulose and/or glycine.

The conjugates of the invention can also be administered in such oral
25 dosage forms as timed-release and sustained-release tablets or capsules, pills, powders, granules, elixers, tinctures, suspensions, syrups, and emulsions.

Liquid, particularly injectable compositions can, for example, be prepared by dissolving, dispersing, *etc.* The active compound is dissolved in or mixed with a pharmaceutically-pure solvent such as, for example, water, saline, aqueous
30 dextrose, glycerol, ethanol, and the like, to thereby form the injectable solution or suspension. Additionally, solid forms suitable for dissolving in liquid prior to injection can be formulated. Injectable compositions are preferably aqueous isotonic solutions or suspensions. The compositions may be sterilized and/or contain adjuvants, such as preserving, stabilizing, wetting or emulsifying agents,

solution promoters, salts for regulating the osmotic pressure and/or buffers. In addition, they may also contain other therapeutically-valuable substances.

The conjugates of the present invention can be administered in intravenous (e.g., bolus or infusion), intraperitoneal, subcutaneous or intramuscular form, all
5 using forms well known to those of ordinary skill in the pharmaceutical arts. Injectables can be prepared in conventional forms, either as liquid solutions or suspensions.

Parental injectable administration is generally used for subcutaneous, intramuscular or intravenous injections and infusions. Additionally, one approach
10 for parenteral administration employs the implantation of a slow-release or sustained-released system, which assures that a constant level of dosage is maintained, for example as described according to U.S. Pat. No. 3,710,795.

Furthermore, the pharmaceutical combinations of the present invention can be administered in intranasal form via topical use of suitable intranasal vehicles,
15 or via transdermal routes, using those forms of transdermal skin patches well known to those of ordinary skill in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen. Other preferred topical preparations include creams, ointments, lotions, aerosols, sprays
20 and gels, wherein the amount administered would be 10-100 times the dose typically given by parenteral administration.

For solid compositions, excipients include pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, magnesium carbonate, and the like may be used. The
25 active compound defined above, may be also formulated as suppositories using for example, polyalkylene glycols, for example, propylene glycol, as the carrier. In some embodiments, suppositories are advantageously prepared from fatty emulsions or suspensions.

The conjugates of the present invention can also be administered in the
30 form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, containing cholesterol, stearylamine, or phosphatidylcholines. In some embodiments, a film of lipid components is

hydrated with an aqueous solution of drug to a form lipid layer encapsulating the drug, as described in U.S. Pat. No. 5,262,564.

The pharmaceutical combinations of the present invention may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyalkylene glycols such as polyethylene glycol and polyethylene glycol derivatives, polyvinylpyrrolidone, pyran copolymer, polyhydroxypropyl-methacrylamide-phenol, polyhydroxyethylaspanamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. The conjugates can also be coupled to proteins, such as, for example, receptor proteins and albumin. Furthermore, the compounds of the present invention may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polyepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

If desired, the pharmaceutical composition to be administered may also contain minor amounts of non-toxic auxiliary substances such as wetting or emulsifying agents, pH buffering agents, and other substances such as for example, sodium acetate, triethanolamine oleate, *etc.*

The dosage regimen utilizing the pharmaceutical combinations of the present invention is selected in accordance with a variety of factors including type, species, age, weight, sex and medical condition of the patient; the severity of the condition to be treated; the route of administration; the renal and hepatic function of the patient; and the particular compound or salt thereof employed. The activity of the compounds of the invention and sensitivity of the patient to side effects are also considered. An ordinarily skilled physician or veterinarian can readily determine and prescribe the effective amount of the drug required to prevent, counter or arrest the progress of the condition.

For any route of administration, divided or single doses may be used. For example, compounds of the present invention may be administered daily or weekly, in a single dose, or the total dosage may be administered in divided doses of two, three or four.

Any of the above pharmaceutical compositions may contain 0.1-99%, 1-70%, or, preferably, 1-50% of the active compounds of the invention as active ingredients.

As described above, the course of the disease and its response to drug treatments may be followed by clinical examination and laboratory findings. The effectiveness of the therapy of the invention is determined by the extent to which the previously described signs and symptoms of a condition are eliminated or substantially reduced.

The present invention is described further by reference to the following, illustrative examples.

EXAMPLE 1
Administration of Idazoxan in Combination with Olanzapine
in Rat Models of Antipsychotic Mechanism of Action

Animals

Adult, male Wistar rats, 200-225 g (B & K Universal, Sollentuna, Sweden) were used. The animals were housed under standard laboratory conditions, on a reversed light/dark cycle (lights off 08:00 am), and allowed 1 week of adaptation to laboratory conditions before being used in experiments. Food and water were available ad libitum.

Drugs

The α_2 adrenergic receptor antagonist idazoxan and the atypical antipsychotic olanzapine were used. Idazoxan was dissolved in physiological saline and olanzapine were dissolved in a minimal (10-20 μ l) amount of glacial acetic acid and made up to volume with 5.5% glucose. Idazoxan was given subcutaneously (s.c.), and olanzapine intraperitoneally (i.p.) in a volume of 2 ml/kg body weight.

Conditioned avoidance response behavior (CAR)

Rats were trained and tested in a conventional, manually operated two-way active avoidance (shuttlebox) apparatus connected to a high resistance power supply. The box was divided into two compartments of equal size by a partition with one opening. Upon presentation of the 80 dB white noise conditioned stimulus (CS), the animals had 10 seconds to move from one compartment of the shuttlebox into the other. If the rat remained in the same compartment for more than 10 seconds, an intermittent electric shock (approx. 0.2 mA of 0.5-sec duration; intershock interval 2.5 sec), the unconditioned stimulus (UCS), was presented in the grid floor until an escape was performed. If the animal did not respond within 50

seconds of the shock period, the trial was terminated (escape failure). Intertrial intervals varied at random between 20 and 40 seconds. The following variables were recorded: *avoidance* (response to CS within 10 sec); *escape* (response to CS+UCS); *escape failures* (failure to respond); and *intertrial crosses*. The animals were trained for 3 consecutive days. Training sessions were run over 15 minutes. A final test session (7.5 minutes) was performed on the day immediately prior to the first experimental day, and only animals performing at the 100% correct level were assigned to the experiment. Experimental manipulations were always preceded by a pretest. All pretest and experimental sessions were run for 7.5 minutes (for further details, see e.g. Wadenberg *et al.* 1990). The same animals were tested repeatedly according to a change-over design (Li 1964) serving as their own controls.

Catalepsy measurements

Animals were observed on an inclined (60°) grid. To establish a reliable baseline, the first 30 s were excluded from the actual rating time. The time the rat remained in the same position was then measured for a maximum of 2.5 min. The catalepsy was scored from 0-5 according to the time (square root transformation) the animal remained immobile (min): 0 = 0-0.08, 1 = 0.09-0.35, 2 = 0.36-0.80, 3 = 0.81-1.42, 4 = 1.43-2.24, 5 = ≥ 2.25 min, *i.e.*, if the rat remained immobile for >2.25 min it was scored as 5, etc (see Ahlenius and Hillegaart 1986).

Statistics

Statistical analysis was performed by means of the Friedman two-way ANOVA by ranks, followed by the Wilcoxon matched-pairs signed-ranks test for comparisons with control conditions (CAR), or the the Kruskal-Wallis one-way ANOVA by ranks followed by the Mann-Whitney *U*-test for comparisons with vehicle treated controls (catalepsy) (Siegel and Castellan Jr 1988).

Results

Figure 1 and Table 1 present the experimental results for this example.

TABLE 1 shows the effects of olanzapine (2.5 mg/kg i.p.) and idazoxan (1.5mg/kg s.c.), alone or in combination, on catalepsy in rats. Shown are CAT ratings \pm semi-interquartile range based on 8 animals per treatment group. Olanzapine and idazoxan did not produce any significant catalepsy compared to vehicle treated controls either alone or in combination.

Table 1

Time after olanzapine 2.5 mg/kg i.p. (hrs)

Drug	0.5	1	2
veh/veh	0 ± 0.5	1.0 ± 0.5	0.5 ± 0.5
ida/veh	0 ± 0.5	0.5 ± 0.5	0 ± 0.3
Veh/ozp	1 ± 2.0	1.5 ± 2.0	1 ± 0.5
Ida/ozp	1 ± 0	0.5 ± 0.5	0.5 ± 0.5

The present series of experiment has used the preclinical CAR and CAT tests with high predictive validity for antipsychotic activity and extrapyramidal side effect (EPS) liability, respectively. It was discovered in rats that adjunctive treatment with a selective α_2 adrenergic receptor antagonist to relatively low doses of a commonly used antipsychotics with low affinity for α_2 adrenergic receptors produced a significant antipsychotic-like effect without catalepsy. Previous data (Wadenberg et al., 2001) have demonstrated that an effective suppression of CAR, i.e. 80-100%, requires about 5 mg/kg of olanzapine in the rat. The present results, obtained by a combination of idazoxan and olanzapine, demonstrate an equally or more effective suppression of the CAR by the use of only 2.5 mg/kg of olanzapine. Thus, these data indicate that the dose of olanzapine required to obtain an effective antipsychotic effect might be reduced by almost 50% through the adjunct treatment with idazoxan. Our results generally predict that if a selective α_2 adrenergic receptor antagonist is given as an adjunct, it may be possible to achieve sufficient antipsychotic effect using a lower dose of an antipsychotic drug than is normally needed when the antipsychotic drug is given alone. Since lower doses of the antipsychotics will generate decreased D2 occupancy, a safer EPS liability profile should be created by the drug combination, as indicated by the present catalepsy results.

EXAMPLE 2

Formulations

Pharmaceutical compositions according to the present invention can
5 include the α_2 -adrenergic receptor antagonist and the atypical antipsychotic in
various proportions. For example, a tablet can include olanzapine and idazoxan in
the proportions of 5mg: 40-80mg. A capsule can include risperidone and
idazoxan in the proportions of 1.5mg: 40-80mg.

EXAMPLE 3

Screening for New Drug Candidates

Prospective pharmaceutical agents useful for the treatment of serious
mental illness according to the present invention can be discovered using a
15 receptor affinity (K_i) profile proportions for the α_2 and D_2 receptors in the
following proportions: 20 nM: 40 nM; 20nM: 100 nM; 15nM: 150 nM.

EXAMPLE 4

Administration of Quetiapine in Combination with Idazoxan

20 Six patients (three males, three females) who meet DSM-III R criteria for
schizophrenia and who have no medical or neurological illness and give informed
consent for a pharmacological study during which quetiapine is administered in
combination with idazoxan with dosage amounts approximating 1000 mg
25 equivalents of chlorpromazine and 120 mg of idazoxan. This translates to a
dosage of quetiapine of 900 mg and a dosage of idazoxan of 120 mg. These
patients are given capsules containing 900 mg of quetiapine and "blinded"
formulation of 120 mg of idazoxan daily for 4 to 6 weeks. Another similar group
of patients is treated with placebo idazoxan capsules.

30 Additionally, another group of patients is treated with quetiapine and
blinded idazoxan at dosages that do not fall within the preferred dosage ranges of
the present invention, i.e., 300mg or 1500 mg of quetiapine and 120 mg idazoxan.

These patients are then evaluated by physicians who are blind to whether
the patient is administered the active drug combination or capsules. This
35 evaluation is effected by the Brief Psychiatric Rating Scale, defined in Overall et
al., Psychol. Rep. 10: 799-812 (1961) and the Simpson Neurological Rating Scale,

defined in Simpson et al., Acta Psychiatr. Scand. 212 (Supp.):9-I 1 (1970) for drug side effects weekly.

Additionally, blood samples are taken to monitor drug plasma levels. Rating Scale total scores are averaged for each group and compared to confirm
5 that the group administered the atypical antipsychotic α_2 antagonist combination in the preferred D_2/α_2 ratio exhibits enhanced rating score reduction relative to the placebo idazoxan group and the group given the same drugs but in dosage ratios not falling within preferred D_2/α_2 ratios

- 25 Many modifications and variations of this invention can be made without departing from its spirit and scope, as will be apparent to those skilled in the art. The specific embodiments described herein are offered by way of example only, and the invention is to be limited only by the terms of the following claims, along with the full scope of equivalents to which such claims are entitled.

30

What is claimed is:

1. A method for treating a serious psychotic mental illness comprising the step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of (i) an α_2 -adrenergic receptor antagonist and (ii) an
5 atypical antipsychotic neuroleptic which has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor in a pharmaceutically acceptable carrier.
2. A method as claimed in claim 1, wherein said α_2 -adrenergic receptor antagonist (i) is selected from the group consisting of idazoxan, yohimbine,
10 ethoxy-idazoxan, fluperoxan and atipamezole.
3. A method as claimed in claim 2 wherein said α_2 -adrenergic receptor antagonist (i) is idazoxan.
4. A method as claimed in claim 1, wherein said antipsychotic neuroleptic drug is selected from the group consisting of olanzapine, risperidone, quetiapine,
15 ziprasidone, sertindole and aripiprazole.
5. A method as claimed in claim 1, wherein said α_2 -adrenergic receptor antagonist (i) is administered in an amount from about 60 to 120 mg/day.
6. A method as claimed in claim 1, wherein said serious psychotic mental illness is schizophrenia.
- 20 7. A pharmaceutical composition comprising a combination of (i) an α_2 -adrenergic receptor antagonist, (ii) an atypical antipsychotic neuroleptic which has a greater antagonist affinity for D₂ dopamine receptor than its antagonist affinity for α_2 adrenergic receptor, and (iii) a pharmaceutically acceptable carrier, wherein the amount of said ingredients (i) and (ii) is therapeutically effective against
25 serious psychotic mental illness.
8. A composition as claimed in claim 7, wherein said α_2 -adrenergic receptor antagonist (i) is selected from the group consisting of idazoxan, yohimbine, ethoxy-idazoxan, fluperoxan and atipamezole.
9. A composition as claimed in claim 8, wherein said α_2 -adrenergic receptor
30 antagonist (i) is idazoxan.
10. A composition as claimed in claim 7, wherein said atypical antipsychotic drug is selected from the group consisting of olanzapine, risperidone, quetiapine, ziprasidone, sertindole and aripiprazole.

11. A method for treating a serious psychotic mental illness comprising the step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of (i) an α_2 -adrenergic receptor antagonist and (ii) an atypical antipsychotic in a pharmaceutically acceptable carrier, wherein
5 said serious psychotic mental illness is selected from the group consisting of Schizophreniform Disorder, Severe Schizoaffective Disorder with Psychotic Features, Bipolar I Disorders with a Single Manic Episode, Severe Bipolar I Disorders with Psychotic Features, Major Depressive Disorders Manifesting a Single Episode, Severe Major Depressive Disorders with Psychotic Features,
10 Bipolar I Disorders Manifesting a Mixed Most Recent Episode, Severe Bipolar I Disorders with Psychotic Features, Brief Psychotic Disorders, Psychotic Disorders NOS, Paranoid Personality Disorders, Schizoid Personality Disorders, Schizotypal Personality Disorders with Sedative, Hypnotic, or Anxiolytic Manifestations, Major Depressive Disorders with Recurrent Episodes, and Psychotic Disorders
15 due to Specific General Medical Conditions.

12. The method as claimed in claim 11, where to said α_2 -adrenergic receptor antagonist (i) is one or more selected from the group consisting of idazoxan, yohimbine, ethoxy-idazoxan, fluperoxan and atipamezole.

13. The method as claimed in claim 11, wherein said atypical antipsychotic
20 drug is selected from the group consisting of olanzapine, risperidone, quetiapine, ziprasidone, sertindole and aripiprazole.

14. The method as claimed in claim 11, wherein said α_2 -adrenergic receptor antagonist (i) is administered in an amount from about 60 to 120 mg/day.

15. A method for treating a serious psychotic mental illness comprising the
25 step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of (i) a compound having combined D_2 dopamine and $5HT_2$ serotonin antagonist activities, wherein said compound (ii) has a greater antagonist affinity for D_2 dopamine receptor than its antagonist affinity for α_2 adrenergic receptor and (ii) a compound having α_2 adrenergic
30 receptor antagonist activity.

16. The method of claim 15 wherein said D_2 dopamine and $5HT_2$ serotonin antagonist is an atypical antipsychotic drug.

17. The method of claim 16 wherein said atypical antipsychotic is selected from the group consisting of olanzapine, risperidone, quetiapine, ziprasidone, sertindole and aripiprazole.

18. The method of claim 15 wherein said α_2 -adrenergic receptor antagonist is
5 selected from the group consisting of idazoxan, yohimbine, ethoxy-idazoxan, fluperoxan and atipamezole.

19. The method of claim 18 wherein said α_2 -adrenergic receptor antagonist is idazoxan.

20. The method of claim 15 wherein said D₂ dopamine and 5HT₂ serotonin
10 antagonist is olanzapine.

21. A method for treating a serious psychotic mental illness comprising the step of administering to a patient in need of such treatment a therapeutically effective amount of a combination of idazoxan and olanzapine.

22. The method of claim 15 wherein the amount of said D₂ dopamine and
15 5HT₂ serotonin antagonist administered to said patient is reduced to approximately 50% of the normally recommended dose.

23. The method of claim 15 wherein said D₂ dopamine and 5HT₂ serotonin antagonist comprises an in vivo D₂ occupancy of approximately 50%.

24. The method of claim 15 wherein the serious psychotic disorder is chosen
20 from the group consisting of schizophreniform disorder, severe schizoaffective disorder with psychotic features, bipolar I disorders with a single manic episode, severe bipolar I disorders with psychotic features, major depressive disorders manifesting a single episode, severe major depressive disorders with psychotic features, bipolar I disorders manifesting a mixed most recent episode, severe
25 bipolar I disorders with psychotic features, brief psychotic disorders, psychotic disorders NOS, paranoid personality disorders, schizoid personality disorders, schizotypal personality disorders, major depressive disorders with recurring episodes, and psychotic disorders due to specific general medical conditions.

25. The method of claim 15 wherein said serious psychotic mental illness is
30 schizophrenia.

26. A method for treating a serious psychotic mental illness in a patient in need thereof which comprises co-administration of (i) a compound having combined D₂ dopamine and 5HT₂ serotonin antagonist activities, wherein said compound has a greater antagonist affinity for D₂ dopamine receptor than its

antagonist affinity for α_2 adrenergic receptor, and (ii) a compound having α_2 adrenergic receptor antagonist activity, wherein said compound (i) is administered initially alone in an amount and for a period of time sufficient to stabilize said patient and subsequently said compound (ii) is co-administered in an amount and
5 for a period of time that allows for a reduction in the amount of compound (i) administered to said patient.

27. The method of claim 26 further comprising the step of reducing the amount of compound (i) administered to said patient after commencing co-administration of compound (ii).

10 28. The method of claim 27 wherein the dose of said compound (i) administered to the patient is reduced to approximately 50% of the dose administered to stabilize said patient.

29. The method of claim 26 wherein the serious psychotic disorder is chosen from the group consisting of schizophreniform disorder, severe schizoaffective disorder with psychotic features, bipolar I disorders with a single manic episode, severe bipolar I disorders with psychotic features, major depressive disorders manifesting a single episode, severe major depressive disorders with psychotic features, bipolar I disorders manifesting a mixed most recent episode, severe bipolar I disorders with psychotic features, brief psychotic disorders, psychotic
15 disorders NOS, paranoid personality disorders, schizoid personality disorders, schizotypal personality disorders, major depressive disorders with recurring episodes, and psychotic disorders due to specific general medical conditions.

30. The method of claim 26 wherein said serious psychotic mental illness is schizophrenia.

25 31. A method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a combination of (i) a compound that blocks or down-regulates D_2 dopamine and $5HT_2$ serotonin receptor activities and (ii) a compound that blocks or down-regulates α_2 adrenergic receptor activity.

30 32. The method of claim 31 wherein said compound (ii) is a norepinephrine reuptake inhibitor.

33. The method of claim 31 wherein said compound (ii) is a selective serotonin reuptake inhibitor.

34. The method of claim 31 wherein said compound (ii) is an anti-sense RNA molecule.

35. A method for treating a serious psychotic disorder in a patient in need thereof which comprises administering an atypical antipsychotic in combination
5 with an effective amount of an α_2 antagonist to provide antipsychotic effects at D₂ receptor occupancy levels of less than or equal to 60%.

36. The method of claim 35 wherein the D₂ occupancy levels are less than or equal to 50%.

37. The method of claim 36 wherein D₂ occupancy levels are measured by
10 positive emission tomography (PET) or single photon emission computerized tomography (SPECT).

38. The method of claim 35 wherein the α_2 antagonist is selected from the group consisting of idazoxan, yohimbine, ethoxy-idazoxan, fluperoxan, and atipamezole.

39. The method of claim of 35 wherein the atypical D₂ antagonist is selected
15 from the group consisting of olanzapine, quetiapine, risperidone, sertindole and ziprasidone.

40. The method of claim 35 wherein the atypical antipsychotic and the α_2 antagonist are administered separately.

41. The method of claim 35 wherein the atypical antipsychotic and the α_2
20 antagonist are administered in combination.

42. The method of claim 41 wherein the atypical antipsychotic and the α_2 antagonist are in different compositions.

43. The method of claim 41 wherein the atypical antipsychotic and the α_2
25 antagonist are in the same composition.

44. The method of claim 35 wherein one or both of the atypical antipsychotic and the α_2 antagonist comprise a mixture of enantiomers of said compounds.

45. The method of claim 44 wherein the atypical D₂ antagonist mixture
30 comprises from 95/5 to 5/95 mole ratios of the enantiomers of the particular atypical antipsychotic compound.

46. The method of claim 44 wherein the α_2 antagonist mixture comprises from 95/5 to 5/95 mole ratios of the enantiomers of the particular α_2 antagonist compound.

47. The method of claim 35 wherein one or both of the atypical antipsychotic and the α_2 antagonist is administered substantially in the form of a single enantiomer.

48. The method of claim 47 wherein the α_2 antagonist is administered
5 substantially in the form of a single enantiomer

49. The method of claim 48 wherein the (+) enantiomer of idazoxan is administered.

50. The method of claim 35 wherein the serious psychotic disorder is chosen from the group consisting of schizophreniform disorder, severe schizoaffective
10 disorder with psychotic features, bipolar I disorders with a single manic episode, severe bipolar I disorders with psychotic features, major depressive disorders manifesting a single episode, severe major depressive disorders with psychotic features, bipolar I disorders manifesting a mixed most recent episode, severe
bipolar I disorders with psychotic features, brief psychotic disorders, psychotic
15 disorders NOS, paranoid personality disorders, schizoid personality disorders, schizotypal personality disorders, major depressive disorders with recurring episodes, and psychotic disorders due to specific general medical conditions.

51. The method of claim 35 wherein the serious psychotic disorder is child or early adolescent schizophrenia.

20 52. The method of claim 51 wherein patient in need of treatment is from about age 9 years to 15 years.

53. The method of claim 51 wherein the serious psychotic disorder is childhood onset schizophrenia.

54. A method for treating a serious psychotic disorder in a patient in need
25 thereof which comprises administering an atypical antipsychotic in combination with an effective amount of a compound which enhances noradrenergic synaptic activity to provide antipsychotic effects at D₂ receptor occupancy levels of less than or equal to 60%.

55. The method of claim 54 wherein the D₂ occupancy levels are less than or
30 equal to 50%.

56. The method of claim 54 wherein D₂ occupancy levels are measured by positive emission tomography (PET) or single photon emission computerized tomography (SPECT).

57. The method of claim 54 wherein the compound which enhances noradrenergic synaptic activity chosen from the group consisting of reboxetine, atomoxetine, or a compound that inhibits the norepinephrine transporter.

58. The method of claim of 54 wherein the atypical D₂ antagonist is selected
5 from the group consisting of olanzapine, quetiapine, risperidone, sertindole and ziprasidone.

59. The method of claim 54 wherein the serious psychotic disorder is chosen from the group consisting of schizophreniform disorder, severe schizoaffective disorder with psychotic features, bipolar I disorders with a single manic episode,
10 severe bipolar I disorders with psychotic features, major depressive disorders manifesting a single episode, severe major depressive disorders with psychotic features, bipolar I disorders manifesting a mixed most recent episode, severe bipolar I disorders with psychotic features, brief psychotic disorders, psychotic disorders NOS, paranoid personality disorders, schizoid personality disorders,
15 schizotypal personality disorders, major depressive disorders with recurring episodes, and psychotic disorders due to specific general medical conditions.

60. The method of claim 54 wherein the serious psychotic disorder is child or early adolescent schizophrenia.

61. The method of claim 60 wherein patient in need of treatment is from about
20 age 9 years to 15 years.

62. The method of claim 60 wherein the serious psychotic disorder is childhood onset schizophrenia.

63. A method of treating a serious psychotic disorder involving the administration of at least one atypical antipsychotic and at least one α_2 adrenergic
25 receptor antagonist wherein the improvement comprises selecting atypical antipsychotics and α_2 receptor antagonists such that the receptor affinity ratios for D₂/ α_2 ranges from about .8 to about 4.5.

64. The method of claim 63 wherein the ratio of D₂/ α_2 ranges from about .85 to about 3.9.

30 65. The method of claim 63 wherein the ratio of D₂/ α_2 from about .95 to about 1.05.

66. The method of claim 63 wherein the ratio of D₂/ α_2 ranges from about .95 to 1.00.

67. The method of claim 63 wherein the ratio of D₂/ α_2 is about 1.0.

68. A method for treating a serious psychotic illness comprising administering at least one atypical antipsychotic and at least one α_2 adrenergic receptor antagonist wherein the dosage balance between the atypical antipsychotic and α_2 antagonist is equivalent to a ratio of 900-1100 mg equivalents of chlorpromazine and an amount of an α_2 antagonist that provides for about equal D_2/α_2 receptor saturation.

69. The method of claim 68 wherein the amount of D_2 antagonist is equivalent to about 950-1050 mg equivalents of chlorpromazine.

70. The method of claim 68 wherein the α_2 antagonist is selected from the group consisting of idazoxan, yohimbine, ethoxyidazoxan, fluperoxan, and atipamezole.

71. The method of claim 68 wherein the atypical D_2 antagonist is selected from olanzapine, quetiapine, risperidone, sertindole and ziprasidone.

72. A method for identifying compounds that are useful to treat serious psychotic mental illness which comprises subjecting a candidate compound to an assay demonstrating affinity for the D_2 dopamine receptor and an assay demonstrating affinity for the α_2 adrenergic receptor and determining that the compound demonstrates significant affinity for both the D_2 dopamine receptor and the α_2 adrenergic receptor.

73. The method of claim 72, further comprising the step of determining that the candidate compound comprises between about 2 to about 15 fold greater affinity for the α_2 adrenergic receptor than for D_2 receptor.

74. The method of claim 72 further comprising the step of subjecting the candidate compound to an assay demonstrating affinity to 5HT₂ serotonin receptors and determining that the compound does not demonstrate significant affinity for the 5HT₂ serotonin receptors.

75. A method for treating a serious psychotic mental illness comprising the step of administered to a patient in need of such treatment a therapeutically effective amount of a compound identified by the methods of any of claims 72-74.

76. A pharmaceutical composition for treating a serious psychotic mental illness comprising a therapeutically effective amount of a compound identified by the methods of any of claims 72-74 and a pharmaceutically acceptable carrier.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US 03/23440

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: —
because they relate to subject matter not required to be searched by this Authority, namely:
see FURTHER INFORMATION sheet PCT/ISA/210
2. ☒ Claims Nos.: —
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
see FURTHER INFORMATION sheet PCT/ISA/210
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☒ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.1

Although claims 1-5,11-75 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

Continuation of Box I.1

Rule 39.1(iv) PCT - Method for treatment of the human or animal body by therapy

Continuation of Box I.2

Present claims 1,5-7,11,14-16,22-37,40-48,50-56,59-68-72-76 relate to a product/compound/method/ defined by reference to a desirable characteristic or property, namely:

- 1) "Alpha-2 adrenergic receptor antagonist"
- 2) "Atypical antipsychotic neuroleptic"

The claims cover all products/compounds/methods having this characteristic or property, whereas the application provides support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT for only a very limited number of such products/compounds/methods. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Independent of the above reasoning, the claims also lack clarity (Article 6 PCT). An attempt is made to define the product/compound/method by reference to a result to be achieved. Again, this lack of clarity in the present case is such as to render a meaningful search over the whole of the claimed scope impossible. Consequently, the search has been carried out for those parts of the claims which appear to be clear, supported and disclosed, namely the compounds specified in claims 2-4,8-10,12,13,17-21,38,39,49,57,58,69-71, with due regard to the general idea underlying the present application.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
